```

with:

- **simulator**: simulator executable file name.

- **evaluator**: Optional. When needed is the evaluator executable file name.
- **seed**: Optional. Seed of the pseudo-random numbers generator (default value is 7007).
- **result**: Optional. It is the name of the optime result file (default name is "result").
- **variables**: Optional. It is the name of all simulated variables file (default name is "variables").
- **precision**: Optional, defined for each variable. Number of precision digits to evaluate the variable. 0 apply for integer numbers (default value is 14).
- **weight** Optional, defined for each experiment. Multiplies the objective value obtained for each experiment in the final objective function value (default value is 1).

Implemented algorithms are:

- **sweep**: Sweep brute force algorithm. It requires for each variable:
 - *sweeps*: number of sweeps to generate for each variable in every experiment.
 The total number of simulations to run is:

$$(\text{number of experiments}) \times (\text{variable 1 number of sweeps}) \times \dots \times (\text{variable n number of sweeps}) \times (\text{number of iterations})$$
- **Monte-Carlo**: Monte-Carlo brute force algorithm. It requires on calibrate:
 - *nsimulations*: number of simulations to run in every experiment.
 The total number of simulations to run is:

$$(\text{number of experiments}) \times (\text{number of simulations}) \times (\text{number of iterations})$$
- Both brute force algorithms can be iterated to improve convergence by using the following parameters:
 - *nbest*: number of best simulations to calculate convergence interval on next iteration (default 1).
 - *tolerance*: tolerance parameter to increase convergence interval (default 0).
 - *niterations*: number of iterations (default 1).
 It multiplies the total number of simulations:

$$\times (\text{number of iterations})$$
- Moreover, both brute force algorithms can be coupled with a direction search method by using:
 - *direction*: method to estimate the optimal direction. Two options are currently available:
 - * *coordinates*: coordinates descent method.
It increases the total number of simulations by:

$$(\text{number of experiments}) \times (\text{number of iterations}) \times (\text{number of steps}) \times 2 \times (\text{number of variables})$$
 - * *random*: random method. It requires:
 - * *nestimates*: number of random checks to estimate the optimal direction.
It increases the total number of simulations by:

$$(\text{number of experiments}) \times (\text{number of iterations}) \times (\text{number of steps}) \times (\text{number of estimates})$$

Both methods require also:

- *nsteps*: number of steps to perform the direction search method,
- *relaxation*: relaxation parameter,

and for each variable:

- *step*: initial step size for the direction search method.

- **genetic**: Genetic algorithm. It requires the following parameters:

- *npopulation*: number of population.
- *ngenerations*: number of generations.
- *mutation*: mutation ratio.
- *reproduction*: reproduction ratio.
- *adaptation*: adaptation ratio.

and for each variable:

- *nbits*: number of bits to encode each variable.

The total number of simulations to run is:

(number of experiments) x (npopulation) x [1 + (ngenerations - 1) x (mutation + reproduction + adaptation)]

```

“json { "towers" : [ { "length" : 50.11, "velocity" : 0.02738, "alpha1" : 179.95, "alpha2" : 179.45, "random" : 0.10,
